

Materiale didattico per partecipante al corso **"TECNICO ESPERTO NELL'ANALISI E NELLA VISUALIZZAZIONE DEI DATI**" – Rif.P.A. 2021-15998/RER – approvata con DGR n. 1263 del 02/08/2021 di IFOA – Istituto Formazione Operatori Aziendali

When we're doing Logistic Regression, the y-axis is converted to the probability that a mouse is obese.

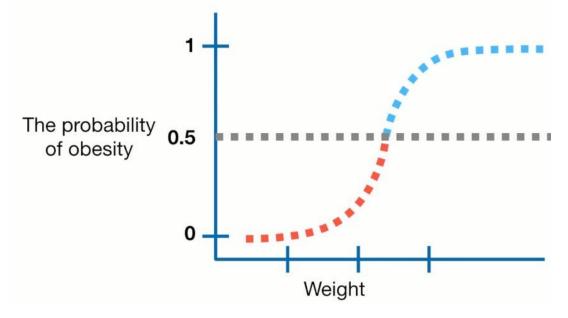

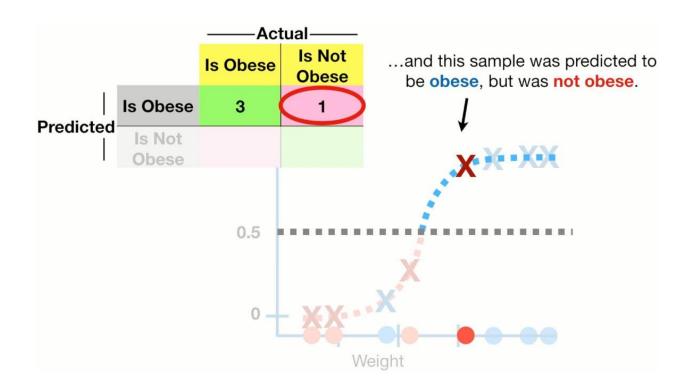

So this Logistic Regression tells us the **probability** that a mouse is **obese** based on its weight.

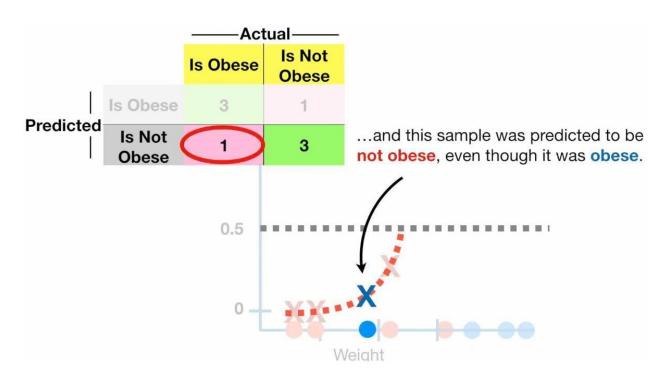

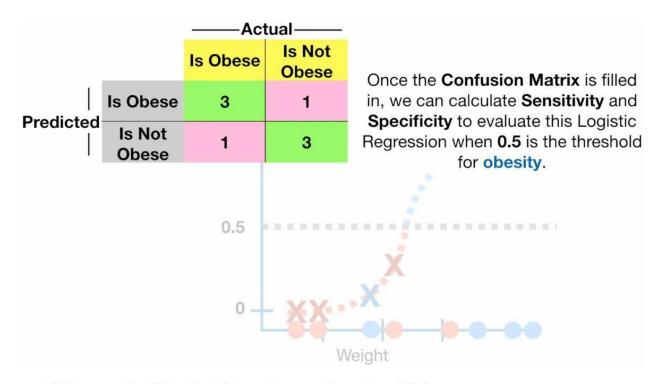

To evaluate the effectiveness of this Logistic Regression, with the classification threshold set to **0.5**, we can test it with mice that we know are **obese** or **not obese**.

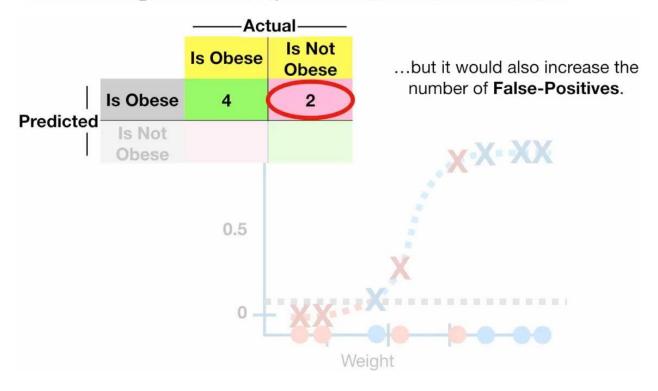

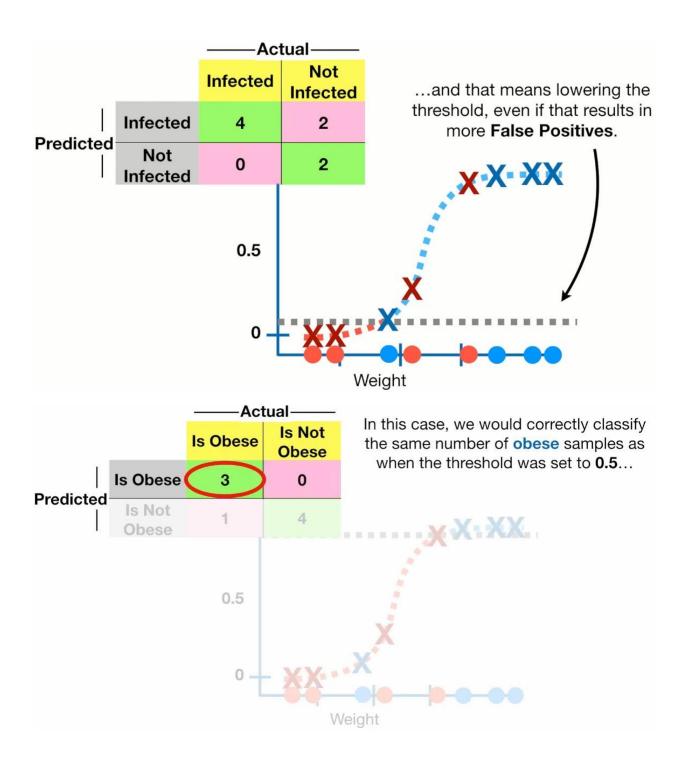

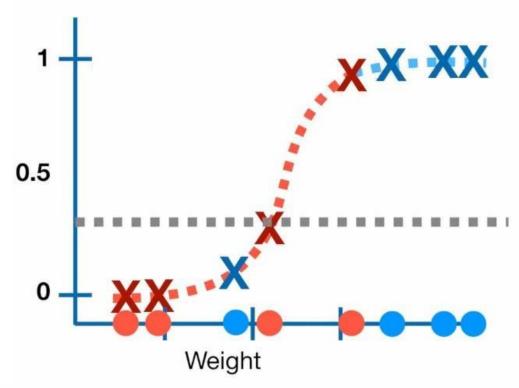

Now let's talk about what happens when we use a different threshold for deciding if a sample is **obese** or **not**.

## ...but the threshold could be set to anything between 0 and 1.

But even if we made one confusion matrix for each threshold that mattered, it would result in a confusingly large number of confusion matrices.

	Is Obese	Is Not Obese	<b>X</b> -X-XX			
Is Obese	4	4				
Is Not Obese	0	0				
0 - XX Weight						

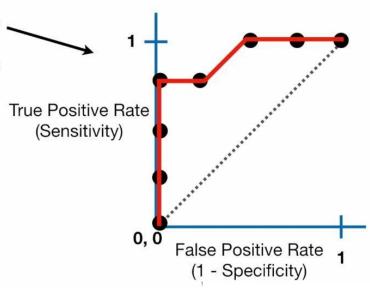

But even if we made one confusion matrix for each threshold that mattered, it would result in a confusingly large number of confusion matrices.

	Is Obese	Is Not Obese	Is Obese	Is Not Obese	(- <b>XX</b>
Is Obese	4	4 Is Obese	4	2	
Is Not Obese	0	ls Not Obese	0	2	
	Is Obese	Is Not Obese	Is Obese	Is Not Obese	
Is Obese	4	(Is Obese	3	2	
Is Not		Is Not			

So instead of being overwhelmed with confusion matrices,

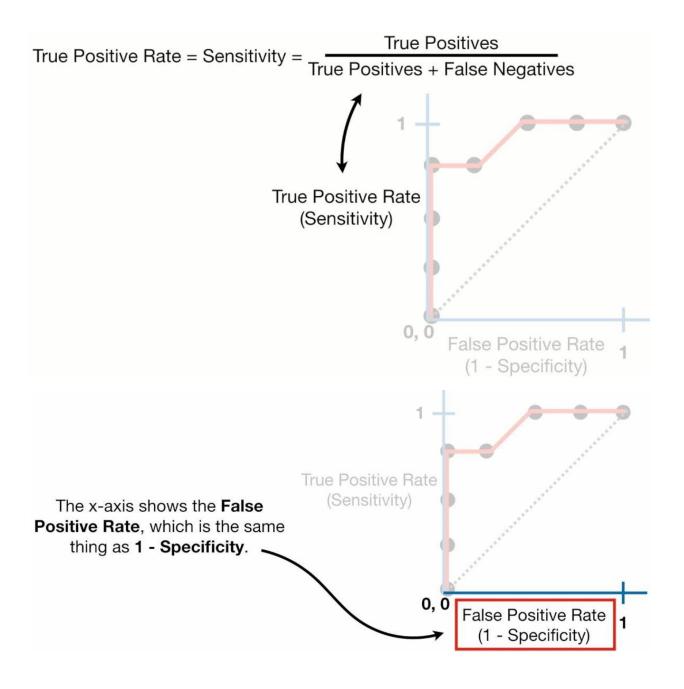

Receiver Operator Characteristic . (ROC) graphs

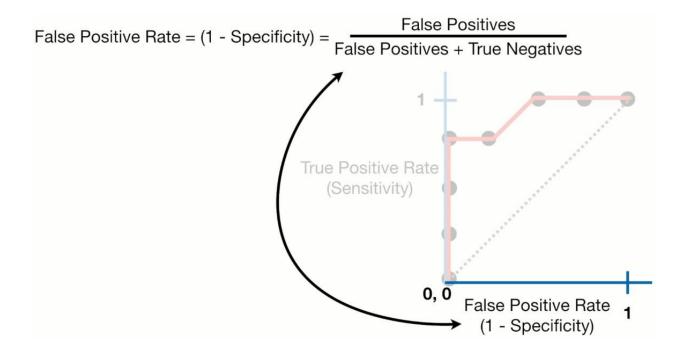

provide a simple way to summarize all of the information.

The y-axis shows the **True Positive Rate**, which is the same thing as **Sensitivity**.

True Positive Rate (Sensitivity)

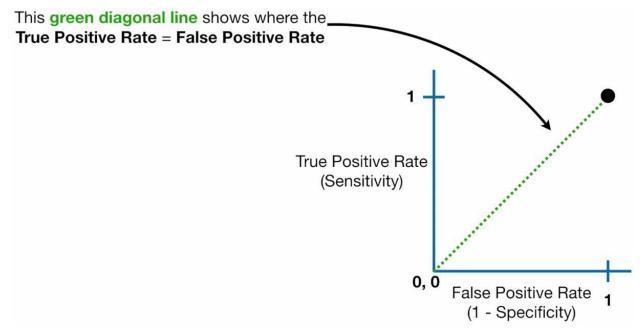

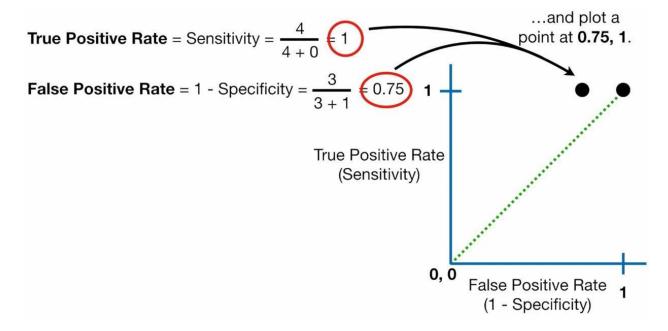

False Positive Rate = 
$$(1 - Specificity) = \frac{False Positives}{False Positives + True Negatives}$$

		——Actual——	
		Is Obese	Is Not Obese
Predicted	Is Obese	True Positives	False Positives
	Is Not Obese	False Negatives	True Negatives

The False Positive Rate tells you the proportion of **not obese** samples that were incorrectly classified and are False Positives.

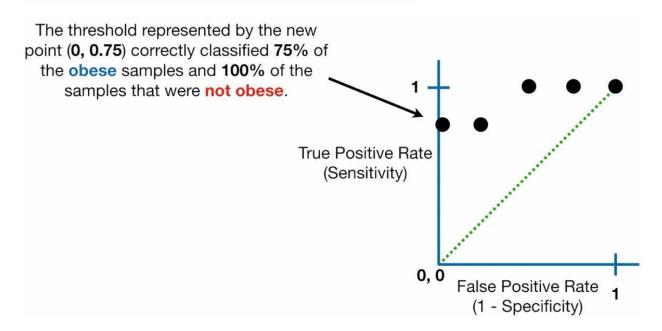

Any point on this **line** means that the **proportion** of **correctly** classified **obese** samples is the same as the **proportion** of **incorrectly** classified samples that are **not obese**.

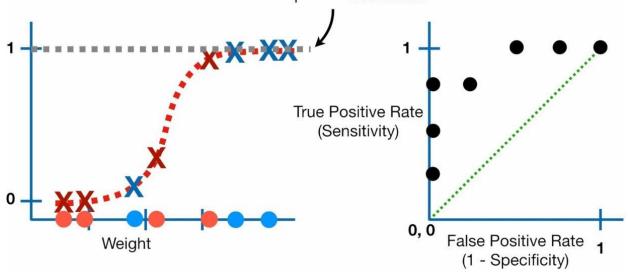

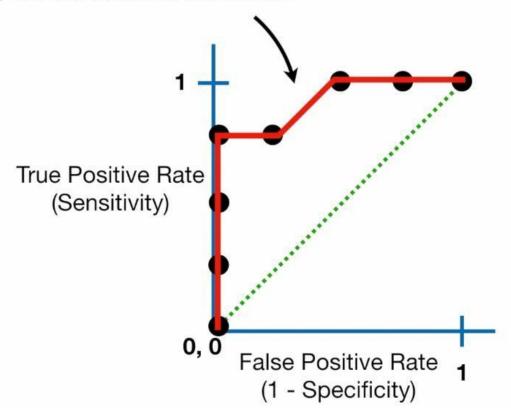

In other words, the new threshold for deciding if a sample is **obese** or **not** is better than the first one.

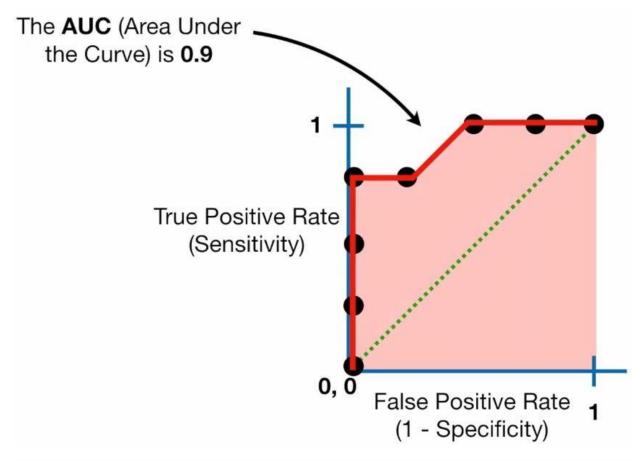

Lastly, we choose a threshold that classifies all of the samples as **not obese**...

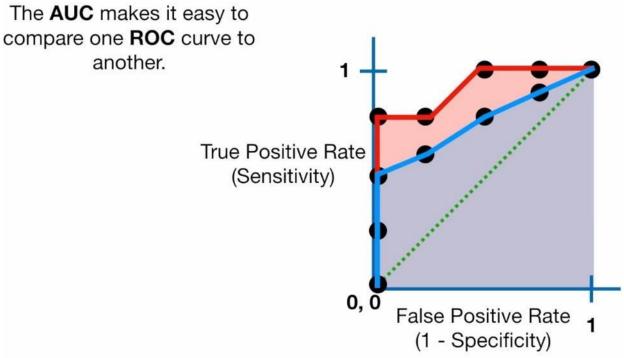

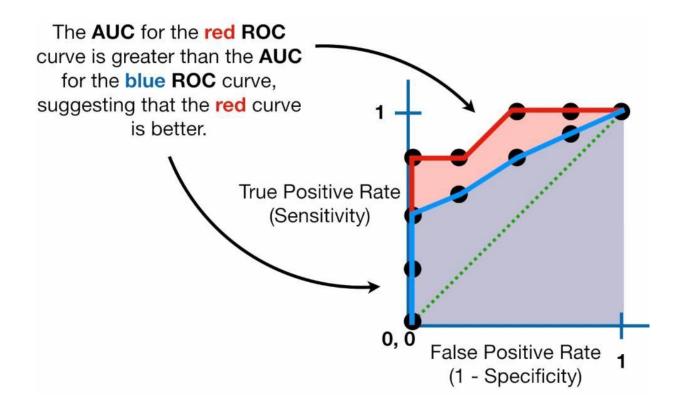

If we want, we can connect the dots...

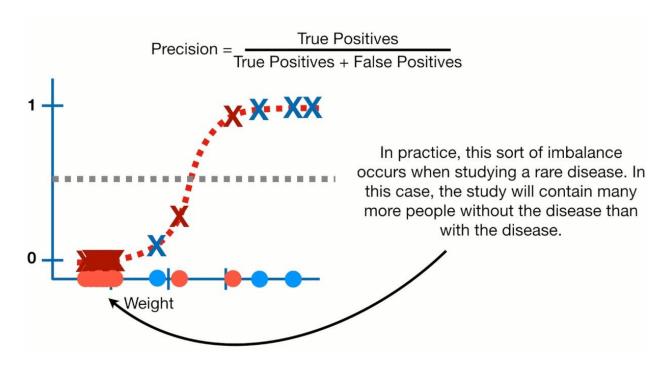

The **ROC** graph summarizes all of the confusion matrices that each threshold produced.

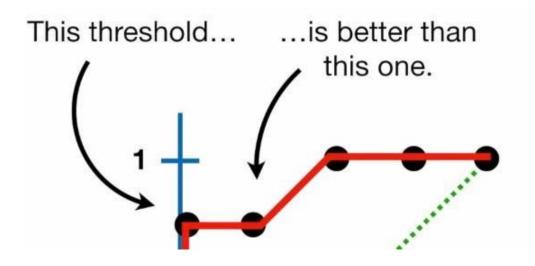

**ROC** curves make it easy to identify the best threshold for making a decision...

...and the **AUC** can help you decide which categorization method is better.
